Subject: Consolidated Update: Claims Reassignment Analysis (Summary of Findings and Updates)
Attachments: Claim Reassignment_Root Cause Assessment.docx; Updated Metrics.docx; 1st Claim_17 Assignments.docx; 2nd Claim_8 Assignments.docx

Importance: High

Hi Team,

To help bring everything into one place, I am summarizing the updates shared over the past few weeks regarding the Claims Reassignment root cause analysis, along with the key findings and supporting materials referenced earlier.

Initial Analysis: January 19, 2026
Reference Document: Claim Reassignment_Root Cause Assessment

Our early analysis indicated that First Time Right (FTR) assignment is approximately 49% across LOBs, meaning nearly half of claims experience at most one assignment.

Key observations from the initial assessment included:

Drivers of Reassignment

- Assignment logic not fully aligned with the current operating model
- Gaps in adjuster profile data (skills, authority limits, availability
- Structural and operational factors such as manual overrides, segmentation, and exposure level assignment

Key Takeaways

- Licensing enforcement is a critical gap and poses compliance risk.
- Hyper segmentation drives unnecessary handoffs and reassignment.
- Manual and named account assignments bypass assignment logic.
- Capacity and experience signals exist but are underutilized.
- Supervisor oversight is essential but inconsistent across teams.
- Round robin logic relies on last updated user ID, which may not accurately reflect last assignment

Opportunity Areas

- Enforce licensing as a hard assignment rule.
- Simplify segmentation and reduce handoffs.
- Incorporate both manual and system assignments in round robin logic.
- Optimize assignments by leveraging adjuster experience and load factor.

- Strengthen assignment accuracy by using true last assignment data instead of last updated timestamps.

The objective of this phase was to determine whether reassignment issues are primarily driven by rule design, data gaps, or operational structure, which will ultimately guide whether the solution path should focus on rule rationalization, analytics driven optimization, or a hybrid approach.

Updated Metrics: January 27, 2026

Reference Document: Updated Metrics

We further analyzed reassignment patterns by separating Straight Through Processing (STP) claims from non-STP claims.

Key findings:

- When STP claims are included, FTR performance appears significantly better
- When STP claims are excluded, reassignment patterns change materially.

Across most LOBs:

- 60-80% of non-STP claims fall into Group C (more than five reassignments)
- Group A (1-2 reassignments) is statistically insignificant, indicating that reassignment events are rarely minor corrections
- This pattern is consistent across Auto, Property, and Liability lines

This suggests that reassignment is structurally embedded in the current operating and assignment model, rather than being limited to isolated exceptions.

Data Considerations in Guidewire: January 29, 2026

The reassignment statistics shared earlier do include transitions triggered by the system, such as assignments based on claim amount, loss cause, or other configured rule conditions.

However, there is an important data limitation in Guidewire that affects how precisely reassignment drivers can be identified.

- At the database level, Guidewire OOTB retains only the current and immediately previous assignee for a claim.
- To analyze assignment transitions over time, we rely on the History table.

One complication is that if a user reassigns a claim using the Use Automated Assignment option, the system records this as a system assignment. As a result, rule driven assignments and user initiated automated assignments are logged the same way, making it difficult to fully distinguish between the two.

Claims Operations Insights: January 30, 2026

Following discussions with the Claims Admin team, we gathered additional operational context that may influence assignment behavior.

1. **Claims Segmentation**

How does Erie segment claims today?

Claims are primarily segmented using **Guidewire rules**, based on:

- Loss cause
- Policy type
- Claim subcomponents (Example: Third party incidents, fixed property damage)

To what extent is segmentation driven by analytics versus adjuster judgment?

Initial segmentation is largely **rules driven**, while adjuster judgment may influence reassignment later in the claim lifecycle.

2. **Team Structure**

How are claims groups organized?

- Organizational structure generally follows:
    - VPs -> Managers -> Supervisors -> Adjusters

- VPs remain at the top of the hierarchy and are associated with high level groups, with managers and supervisors nested beneath them.
- Exact structure varies depending on:
    - Number of supervisors
    - Number of direct reports per supervisor

How many adjusters are typically in a group, and how many supervisors oversee them?

- Average span of control is approximately 7 to 10 adjusters per supervisor.
- When users are added to a group, several role attributes are configured, such as:
    - Member Yes or No
    - Admin Yes or No
    - Manager Yes or No
- These roles and attributes directly influence which claims a user can receive through assignment logic.
- Each group has a single designated supervisor, although supervisors may also function as group members

How are supervisors assigned to groups?

- Supervisor group assignment is driven primarily through HR systems.
- Updates flow from HR or field leadership via data change forms.
- These updates:
    - Feed systems like Outlook and PeopleSoft
    - Do not always fully align with Claim Center group structures, resulting in occasional mismatches between HR data and ECC configuration.

3. **Adjuster Profiles and Qualifications**

How are adjuster HR profiles managed and updated?

- Claims Admin receives an HR report every two weeks.
- Authority limits and related profile updates are adjusted based on this report.

Are certifications, experience, and skill attributes standardized across adjusters?

- Standardization exists primarily at the job title or functional position level.
- Job titles map to predefined attributes
- Hiring managers provide input during onboarding to align role and attributes.

How does the organization handle differences in adjuster experience levels?

- Experience level is not explicitly differentiated or granularly tracked beyond role and title.
- Supervisors play a key role in managing workload and oversight for less experienced adjusters.

Is the HR profile fully in sync with the ECC user profile?

- Profiles are reconciled on a biweekly cadence using HR reports.
- While updates are frequent, the sync is not real time.

Current Assignment Metrics at Erie: February 5, 2026

We also explored whether reassignment metrics are formally tracked.

Current tracking is limited to claims that were initially assigned to a supervisor and later reassigned to an adjuster

Other forms of reassignment are not currently tracked as formal metrics, though there may be additional insights available through further data exploration.

Claim Level Case Studies: February 6, 2026
Reference Documents: 1st Claim_17 Assignments, 2nd Claim_8 Assignments

To complement the broader metrics, we analyzed two representative claims with multiple assignment transitions.

- **Example 1:**
  - 17 assignments
  - Claim status: Open
- **Example 2:**
  - 8 assignments
  - Claim status: Closed

1. In one case, the initial routing aligns correctly with the loss location, while subsequent reassignments for both claims are largely driven by claim evolution, functional handoffs, and the operating model structure.

2. Both cases experienced repeated back and forth assignments, with one claim ultimately settling with a handler who was already involved earlier. This highlights opportunities to improve first time right assignment and reduce rework.

The attached documents provide detailed assignment timelines and analysis for your reference. These examples are intended to complement the broader metrics.

Overall, the analysis so far suggests reassignment patterns are influenced by a combination of:

- Assignment rule complexity
- Operating model design and segmentation
- Limited use of adjuster skill, capacity, and authorization signals in routing decisions

Regards,
Abhilash Hota
